Abstract

A working group of investigators, who are characterizing and quantifying the organic compounds in particulate matter (PM) as part of the US EPA's PM 2.5 research program and related studies, was established to advance the quality and comparability of data on the organic composition of PM. This group has completed two interlaboratory comparison studies. The first study used a subset of SRM 1649a (Urban Dust, sieved to <123 µm) that had been sieved to <63 µm (Air Particulate I) as an unknown PM sample. In addition to Air Particulate I, the participants received a dichloromethane extract of Air Particulate I as a second unknown sample and a sample of SRM 1649a for use as a control material. For the second study, the participants received a sample of PM2.5 collected recently in Baltimore, MD along with a sample of SRM 1649a. The target analytes include polycyclic aromatic hydrocarbons (PAHs), nitrated PAHs, alkanes (including hopanes and cholestanes), sterols, carbonyl compounds (ketones and aldehydes), acids (alkanoic and resin), phenols, and sugars. Because this is a performance-based study, laboratories are encouraged to use the methods that they are routinely using in their laboratories to analyze similar samples. The consensus values, accuracy and precision assessments, and the methods used by each laboratory are summarized in this report.

Introduction

Organic chemicals adsorbed to fine particulate matter (PM) in the ambient air account for a major component of the PM mass and include source tracers as well as toxic compounds that may contribute to adverse human health effects. A working group of PM investigators from the US Environmental Protection Agency (EPA) Supersites and related research programs was established to improve the quality and comparability of data on the organic composition of aerosols. The working group is known as the PM2.5 Organic Speciation Working Group and includes researchers involved in the EPA PM Supersites and related sites, EPA PM centers, national laboratories and other research centers, as well as regional and state laboratories. The goal of the working group is to improve the characterization and quantification of organic compounds associated with fine PM through participation in interlaboratory comparison exercises and provide input for the development of appropriate SRMs. Improvements in the quality of organic measuerments will allow the comparison of organic species across geographic regions and will aid in source receptor modeling, in relating toxicity and health outcomes to specific organic species, and in assessing human exposure to specific organic species and sources.

To aid in this effort, the National Institute of Standards and Technology (NIST) is coordinating a series of interlaboratory trials using interim reference materials through the Intercomparison Exercise Program for Organic Contaminants in PM2.5 Air Particulate Matter. The initial interlaboratory trial utilized PM from a bulk portion of Standard Reference Material (SRM) 1649a Urban Dust, that had been sieved to less than 63 µm, and an extract of these particles. The original SRM 1649, collected in Washington, DC and issued in 1982, was reissued as SRM 1649a in 2000. SRM 1649 and SRM 1649a were sieved to less than 123 µm when prepared. The second interlaboratory trial utilized a PM2.5 (2.5 µm, aerodynamic diameter) sample recently collected in Baltimore MD. Results from these trials will provide the basis for improved quality assurance (QA) measures and methods for characterizing the PM-associated organic matter. The target organic analytes vary among the participants and include: alkanes (including hopanes and cholestanes), alkenes, aromatic and polycyclic aromatic hydrocarbons (PAHs), nitrated PAHs, sterols, carbonyl compounds (e.g., ketones and aldehydes), acids (alkanoic and resin acids), phenols, methoxyphenols, and sugars. The participating laboratories are not constrained by a specific analytical method; however, the laboratories are requested to summarize the methods used so that the results from different methods can be compared.

The first interlaboratory comparison study (Trial I) of the PM2.5 Organic Speciation Working Group was initiated in February 2001. The purpose of the interlaboratory study was to: (1) determine the comparability of measurements for various organic analytes among the participants and (2) establish consensus reference values for the interim reference materials and SRM 1649a for species not previously value assigned by NIST. A secondary objective was to determine if the interlaboratory variability was decreased by providing a solvent extract of the particles compared to analysis of the particles. Trial I used existing SRM 1649a bulk material that had been sieved to less than 63 μ m and a solvent extract of this material. SRM 1649a was analyzed as the control sample. The trial results from 14 participating laboratories and summary statistics were first reported at an Organic Speciation Working Group meeting held during the American Association for Aerosol Research (AAAR)

Conference in October 2001. Because it was a requirement that all participants return data on the particulate sample used for the first trial prior to receiving the materials for the second trial (a sample of PM2.5 collected in Baltimore, MD plus SRM 1649a as a control), an additional nine laboratories have returned data for Trial I since the October 2001 meeting.

The second interlaboratory comparison study (Trial II) using a Baltimore sample of PM2.5 collected during 1998, 1999, and 2001 and SRM 1649a as a control was initiated in March 2002. As mentioned above, these samples were sent only to those participants who returned data for the particulate sample used in Trial I. A brief discussion of percent differences among the seven laboratories who had reported results for Trial II by October 2002 was held at the Organic Speciation Working Group meeting convened during the AAAR Conference in October 2002. Since then, an additional 11 laboratories have reported data for Trial II. The Trial I and Trial II results and summary statistics for all of the laboratories reporting results to date are detailed in this report.

Sources and Preparation of Materials used in Intercomparison Trial I

The air particulate extract was prepared from bulk SRM 1649 Urban Dust that has been resieved to $<63~\mu m$. The original SRM 1649 (currently available as SRM 1649a) was collected in the Washington, DC area over a period in excess of 12 months using a baghouse. The material was removed from the baghouse filter bags and combined in a single lot. The lot was passed through a 125 μm sieve. The sieved material was mixed in a V-blender.

For the extract, each of 10 pressurized fluid extraction cells was filled with Hydromatrix mixed with 1 g of air particulate matter and fitted with three filters on the exit side. The extractions were performed using the following conditions:

Solvent: dichloromethane

Heat: 100 °C for 5 min

Pressure: 2000 psi

Static cycles: three at 5 min each

Flush: 90 % volume

Purge: 180 s

The extracts from the 10 cells were combined and concentrated to 100 mL, and the extractions were performed for a second set of 10 cells. The combined extract (200 mL) was then ampouled with approximately 1.2 mL of extract per ampoule. Each 1 mL of extract represented approximately 0.1 g of air particulate matter. This extract was labeled as QA01EXT01-Air Particulate Extract I. Some of the bulk air particulate used to make the extract was bottled (500 mg per bottle) and labeled as QA01APT01-Air Particulate I. In addition, SRM 1649a was rebottled with approximately 500 mg per bottle. One bottle each of QA01APT01 and SRM 1649a and five ampoules of QA01EXT01 were sent to each of the laboratories participating in the Intercomparison Exercise Program for Organic Contaminants in PM2.5 Air Particulate Matter. The instructions and data sheet that accompanied the samples are provided in Appendix A. In the letter accompanying each shipment, each participant was asked to analyze each of three replicate samples and to concurrently analyze the NIST SRM 1649a Urban Dust.

Sources and Preparation of Material used in Intercomparison Trial II

The PM2.5 material was collected in Baltimore City, MD at the location of the primary sampling site for the Baltimore PM Supersite [1] in the vicinity of major Baltimore industries, e.g., incinerators and factories to the south and southwest and also several major highways to the west and east. The bulk of the material (approximately 90 %) was collected in the winter of 1998-1999 with the remainder being collected in January 2001. The sampling apparatus is an Ultra-High-Volume Sampler (UHVS), consisting of an air inlet, cyclone separator, filter cassettes, and a regenerative blower. The fine particles (2.5 µm, aerodynamic diameter) were separated in the high volume cyclone sampler and collected onto an array of Teflon membrane filters. At the end of each collection, the filters were exchanged in a trailer with temperature and humidity control. The loaded filters were brought back to NIST where the air particulate was brushed off the filter inside a plexiglass glove box. The total amount of air particulate collected for use as the PM2.5 Interim Reference Material (RM) was 21.93 g. This material was placed in a 1 L glass bottle and mixed for 3 h on a bottle roller. The material was then aliquoted into approximately 100 mg portions in amber bottles with Teflon-lined lids. A total of 198 bottles of PM 2.5 Interim RM were prepared. One bottle each of PM 2.5 Interim RM and SRM 1649a (approximately 500 mg) were sent to each of the laboratories participating in Trial II. The instructions and data sheet that accompanied the samples are provided in Appendix A. In the letter accompanying each shipment, each participant was asked to analyze each of three replicate samples and to concurrently analyze the NIST SRM 1649a, Urban Dust. Twelve aliquots of the material were analyzed by instrumental neutron activation analysis for elemental composition. The iron was found to be very high (195 g/kg with a standard deviation of 4 g/kg for the 12 aliquots). [2]

Evaluation of Exercise Results

Establishment of the Assigned Values

The following guidelines were used by the NIST exercise coordinators for the establishment of the exercise "Assigned Values" for these exercises. The laboratory's performance on concurrent reference material analyses was used to determine if that laboratory's results would be included in the calculation of the exercise assigned value for the unknown material for a particular analyte. The results reported for the unknown materials from laboratories that did not report results for the reference materials were not used in these calculations. After the exercise assigned values, standard deviations, and 95 % confidence limits had been calculated, all reported results for the Air Particulate Extract I, Air Particulate I, and PM2.5 Interim RM materials were evaluated relative to these exercise assigned values.

Laboratory data submission: Each participating laboratory was to submit data from three replicate determinations of the unknown materials (Air Particulate Extract I, Air Particulate I, and PM2.5 Interim RM) and were requested to report results of concurrent analyses of NIST SRM 1649a. Laboratories were requested to report these results to three significant figures and to provide brief descriptions of their extraction, cleanup, and analytical procedures.

Determination of laboratory analyte means: For each laboratory, the laboratory analyte mean of the three sample results (S1, S2, and S3) was calculated for each analyte. Non-numerical data were treated as follows: A mean "<value" was used when three "<values" were reported; NA (not analyzed/determined) was used for three reported NAs, etc.; and, if the reported results were of mixed type, e.g., S1 and S2 were numerical values and S3 was reported as "<value", the two similar "types" were used to either determine the mean or to set a non-numerical descriptor.

Determination of assigned values: For a particular analyte, the performance on the reference material was deemed acceptable for the purpose of these exercises if the laboratory result was within 30 % of the upper and lower limits of the confidence interval for analytes listed as certified or reference values in the Certificate of Analysis for SRM 1649a. For each analyte of interest not listed as a certified or reference value in SRM 1649a, no target concentration was used. If a laboratory demonstrated acceptable performance on a particular analyte in the reference material, the laboratory's results for that analyte in the corresponding "unknown" exercise material were then used in the calculation of the analyte's exercise assigned value unless the mean was deemed an "outlier." For evaluation of potential outliers, statistical tests and expert analyst judgement were used after viewing both normal and log plots of the data. This judgement utilized knowledge of potential coeluters based on the laboratory's reported methods.

Reported Results

Laboratories were assigned numerical identification codes in order of receipt of data for Trial I with the exception of NIST-Gaithersburg, which is Laboratory 1 in these exercises, and NIST-Charleston which is Laboratory 13 in these exercises. A laboratory was assigned the same code for each material, including the PM2.5 Interim RM in Trial II. A list of participating laboratories in alphabetical order is given in Appendix G. In this report, the laboratory mean replicate data are shown in Tables 1, 2, and 3 for Air Particulate Extract I, Air Particulate I, and SRM 1649a reported with Trial I, respectively, and in Tables 9 and 10 for PM2.5 Interim RM and SRM 1649a reported with Trial II, respectively. Included in these tables are the exercise assigned values, the standard deviation of the assigned value, and the percent relative standard deviation (% RSD). Notes included by a laboratory with its data are listed in Appendix B. Summaries of the methods used by each laboratory are in Appendix C.

In Appendices D (Air Particulate Extract I), E (Air Particulate I), and F (PM2.5 Interim RM), charts of the mean reported numerical results by laboratory for **each analyte** for which more than two laboratories reported data are shown for the exercise material and the corresponding reference material.

Performance Scores

The exercise coordinators recognize that different programs have different data quality needs. The acceptability of the results submitted by a particular laboratory will be decided by the individual program(s) for which the particular laboratory provides data. Typically, the program will use these exercise results in conjunction with the laboratory's performance in the analysis of certified reference materials and/or control materials, and of other quality assurance samples. These exercise results are

shown in a number of ways in this report to facilitate their use by these programs in their acceptability assessments.

IUPAC guidelines [3] describe the use of z-scores and p-scores for assessment of accuracy and precision in intercomparison exercises such as those described in this report. These indices assess the difference between the result of the laboratory and the exercise assigned value and can be used, with caution, to compare performance on different analytes and on different materials.

Accuracy Assessment (z-score)

The z-score is a bias estimate divided by a performance criterion so that $z = (x - X)/\sigma$ where x is the individual laboratory result, X is the "Exercise Assigned Value," and σ is the target value for standard deviation. As described in the IUPAC guidelines, the choice of σ is dependent upon data quality objectives of a particular program. It can be "fixed" and arrived at by perception, prescription, or reference to validated methodology (e.g., $\sigma = 0.025$ X, X is the analyte concentration), or it can be an estimate of the actual variation (e.g., the calculated standard deviation, s, from the exercise data). The "fixed" performance criterion is more useful in the comparison of a laboratory's performance on different materials while the use of the actual variation may be more useful within a given exercise, for example, if the determination of a particular analyte is more problematic than usual.

We have calculated and reported z-scores using both approaches for each analyte for each laboratory. At a previous workshop, it was decided to use "25 % of the exercise assigned value" as the fixed target value for standard deviation for this program, at least for the initial exercises. We also calculated z-scores based on "one assigned-value standard deviation, s." The z-scores calculated for these exercises can thus be interpreted as shown in the following examples:

z-score (25 % X): +1 -2	laboratory result is 25 % higher than the assigned value laboratory result is 50 % lower than the assigned value
z-score (s):	
+1	laboratory result is one "exercise standard deviation" higher than the assigned value
-2	laboratory result is "two exercise standard deviations" lower than the assigned value

From a scientific point of view, IUPAC does not recommend the classification of z-scores but allows that it is possible to classify scores, e.g.:

$ z \leq 2$	Satisfactory
2 < z < 3	Questionable
ız ı≥ 3	Unsatisfactory

Tables 4 and 5 show the z-scores using 25 % and s, respectively, for the Air Particulate Extract I, Tables 6 and 7 show the z-scores using 25 % and s, respectively, for the Air Particulate I, and Tables 11 and 12 show the z-scores using 25 % and s, respectively, for the PM2.5 Interim RM.

Precision Assessment (p-score)

The p-score is defined as an individual laboratory's coefficient of variation (relative standard deviation for three measurements) divided by a target coefficient of variation (CV). Participating laboratories analyzed the three replicate samples for an exercise with the same sample set, i.e., one set of samples with the same blank, calibration curve, etc. applicable for each. Since the repeatability for replicates within a set is generally better than for replicates in different sets, this does not result in data that are very useful for precision (repeatability) assessment. For the calculation of p-scores for this program, the current target CV for the three replicates is 15 % so a p-score of 1 indicates that the laboratory's CV for the three subsamples was 15 %. Table 8 shows the calculated p-scores for each laboratory for each reported analyte for Trial I, and Table 13 shows the calculated p-scores for each laboratory for each reported analyte in Trial II.

Discussion

Trial Results

Laboratories were requested to quantify a wide variety of analytes in this study (See Table 1 in Appendix A). Twenty-three laboratories submitted data for Trial I, nine of those laboratories after the original meeting in October 2001, with the most extensive data set for the PAHs. The nine laboratories (identified as 15 through 23) reporting after the October 2001 meeting were not requested to report data for the Air Particulate Extract I, although one laboratory (16) did report data for two nitrated-PAHs in Extract I. Laboratories were requested to report their results in ng/g extract for Air Particulate Extract I and in ng/g particulate matter for Air Particulate I and SRM 1649a. Laboratories 2, 3, 4, 5, 6, 7, 8, 9, 11, 12, and 14 used a density to convert their results to ng/g extract for Air Particulate Extract I. The densities used ranged from 1.33 g/mL to 1.36 g/mL except for laboratory 12 which used the density of acetonitrile, 0.786 g/mL. The exercise coordinator converted their data using a density of 1.33 g/mL to make the data comparable to the other results. Laboratory 6 reported their data in terms of 0.1 g of particulate so the exercise coordinator converted their data by multiplying by 10. Laboratory 5 reported their data in terms of ng/mg so the exercise coordinator converted their data by multiplying by 1000. Laboratory 14 reported their data for the extract in terms of µg/mL and in terms of µg/g for the particulate and SRM 1649a in terms of µg/g. The exercise coordinator used a density of 1.33 g/mL to convert the extract concentration on a mass per volume basis to a per gram basis and multiplied all the data by 1000 to convert to ng/g. No other changes were made by the exercise coordinator for the Air Particulate I or SRM 1649a data.

The agreement among the laboratories is similar for both Particulate I and Extract I; therefore, only a particulate sample will be used in future exercises. For Extract I, 78 % of the PAH data are within 25 % of the assigned value (Table 4) while for Particulate I, 74 % of the PAH data are within 25 % of the assigned value (Table 6). With three or fewer laboratories reporting data for the other compounds, z-scores were not calculated. The precision data are presented in Table 8. Since the laboratories, in general, ran the samples in one batch the p-scores only indicate a within-batch

precision, which is generally better than an inter-batch precision.

Laboratories were requested to quantify a similar set of analytes in Trial II as in Trial I (See Appendix A for the list). Eighteen laboratories submitted data. Because laboratories were required to submit data for the particulate sample used in Trial I prior to receiving the samples for Trial II, the assigned laboratory numbers for the two exercises are the same. No changes were made by the exercise coordinator to the data submitted.

The z-scores and p-scores for both trials are summarized by laboratory in Table 14 by laboratory along with the number of compounds measured by each laboratory. Overall, there were 70 % of the z-scores (25 %) that were \leq 1 for the Air Particulate Extract I, 65 % for the Air Particulate I, and 47 % for the PM2.5 Interim RM. The largest discrepancies among laboratories were for those compound classes for which only a limited number of laboratories reported results. In general, the p-scores tracked from the "unknown" samples to SRM 1649a. In other words, the laboratories that had a high percentage of p-scores \geq 3 for the "unknown" samples also tended to have a high percentage of p-scores \geq 3 for SRM 1649a.

In Table 15, the results for SRM 1649a from Trial I and Trial II are compared to the certified and reference concentrations for the PAHs, to values assigned for the nitrated-PAHs based on the data from Trials I and II along with data from Bamford and coworkers [7], and to each other for the remaining compound classes. The agreement for the PAHs is relatively good. For the other compound classes, however, there are high standard deviations within each trial and large differences between the trials as high as 100 %. To help address these differences, calibration solution SRMs are under development for a number of the compound classes based on a priority list established by the working group. The first of these calibration solutions, i.e. aliphatic hydrocarbons, will be available for the third trial set that began in Summer 2004.

Intercomparison exercises provide an important mechanism for assessing the comparability, accuracy, and reproducibility of results from the participating laboratories. Exercise materials similar in matrix, form, and analyte concentration to typical samples routinely analyzed by the laboratories are most useful for demonstrating the level of comparability and for revealing potential problem areas. Minimizing the between-laboratory bias so that the analytical variability is significantly less than the sampling variability should be an achievable goal.

Problems and Potential Solutions for Improving Quantification of Target Analytes

PAHs: Nineteen laboratories returned data for selected PAHs in Trial I while fourteen laboratories returned data for selected PAHs in Trial II. This is the largest data set received for any of the analyte groups. PAH analysis is fairly well-established with a number of commercial sources for neat chemicals of stated purity as well as a number of commercial sources of reliable calibration solutions. In addition, SRMs exist for PAHs in solution as well as natural matrices such as air particulate matter and sediment. Some problems were noted for individual analytes, however. There was a wide variation in the data received for naphthalene, ranging from 100 ng/g to 7400 ng/g in the Air Particulate I sample and from 40 ng/g to 2500 ng/g in the PM2.5 Interim RM sample. Naphthalene is a volatile compound, so it is important to have an internal standard/surrogate added

to the samples that will mimic the behavior of naphthalene during the sample preparation steps, preferably carbon-13 or deuterium labeled naphthalene. The majority of the laboratories reporting data for chrysene neglected to note a coelution with triphenylene. These isomers coelute on most gas chromatographic phases, but they can be partially separated using a 60 m nonpolar column (5% mole fraction) phenyl methylpolysiloxane phase) and almost baseline separated using a 60 m proprietary phase (DB-XLB), both with a slow temperature program. [4] A number of laboratories also misidentified the benzofluoranthene isomers. There are three isomers that elute close to one another, the b, j, and k isomers. Typically, benzo[b]fluoranthene and benzo[j]fluoranthene coelute on the nonpolar columns, including the DB-XLB mentioned above. A moderately polar 50% phenyl methylpolysilxoane phase, however, will separate the isomers, changing the elution order for the benzo[j] and benzo[k]fluoranthenes. [4] A combined concentration for dibenz[a,h]anthracene and dibenz[a,c]anthracene was also commonly reported by the participants dibenz[a,h]anthracene. These two isomers coelute on the non-polar phases but can be separated on the moderately polar phases. There were only very limited data (five sets or less) received for some of the potentially more interesting PAHs, including the methylphenanthrenes, retene, coronene, and dibenzo[a,e]pyrene. As calibration solutions become available for these additional compounds, it is hoped that more laboratories will include them in their analyses.

Nitrated-PAHs: Only three laboratories returned data for the nitrated-PAHs in Trial I (one of those laboratories returned two data sets), and four laboratories returned data for the nitrated-PAHs in Trial II. Except for 6-nitrobenzo[a]pyrene, the agreement was good with the laboratory means agreeing to within 15% of each other for all of the nitrated-PAHs targeted except 7-nitrobenz[a]anthracene in the PM2.5 Interim RM (relative standard deviation for the laboratory means of 25%). Two laboratories returned data for 6-nitrobenzo[a]pyrene. For Air Particulate I and SRM 1649a, laboratory 1 reported values lower than their detection limit while laboratory 6 reported two sets of data, the first one more than an order of magnitude higher in concentration than the second value. For the PM 2.5 Interim RM used in Trial II, however, laboratory 1 reported a mean value of 312 ng/g while laboratory 6 reported a mean value of 24.3 ng/g. Hopefully, additional laboratories will return data for the nitrated-PAHs in future intercomparison exercises.

Alkanes and alkenes: Ten and eleven laboratories, respectively, returned data for selected alkanes in Trials I and II. No data sets were returned for the alkenes. It should be noted that prior to starting Trial II, the target analyte list for the alkanes was increased to include odd chain length alkanes from C21 through C31. Only even chain length alkanes were included in the Trial I target analyte list. For both trials, there was a large spread in the data reported for the alkanes with relative standard deviations of the consensus means ranging from 30 % for *n*-C20 in Air Particulate 1 to 130% for *n*-C28 in PM2.5 Interim RM. This spread in the alkane data is probably due to the non-specificity of the mass spectral ion/ions that are used to monitor alkanes. The alkanes tend to fragment in the mass spectrometer resulting in low relative molecular mass (<100) fragments that are commonly used to identify and quantify the alkanes. Other substituted alkanes, however, may fragment to a similar pattern resulting in misidentification. In addition, alkanes are commonly found in laboratory blanks so overestimation of the alkane concentrations is a possibility if blanks are not monitored.

Hopanes, cholestanes, and sterols: As with the alkanes, the target analyte list for the hopanes, cholestanes, and sterols was expanded from 13 to 15 analytes between Trial I and Trial II. Seven

laboratories (not the same seven in both trials) reported data for this class of compounds in the two trials. The spread of the data for the two trials is from 14 % relative standard deviation for 17a(H),21b(H)-29-norhopane in the Air Particulate I sample to 75 % for 17a(H),21b(H)-29-hopane in the PM2.5 Interim RM. As for the alkanes, there is one mass spectral fragment ion that is typically used to quantify the hopanes (191) and two that are typically used to quantify the steranes (217 and 218). Due to the lack of available standards, the correct identification of the hopanes and steranes is an issue.

Carbonyls and acids: Seven laboratories returned data for selected carbonyls and acids in Trial I and four laboratories in Trial II. For a majority of the analytes, only one or two laboratories returned data so standard deviations for consensus values could only be calculated for four compounds in Trial I and two compounds in Trial II. For those compounds, however, the relative standard deviations of the consensus values were all > 50 %. Due to the polarity of these compounds, there are additional analytical challenges, both in extraction and isolation from the matrix. Many of these compounds need to be derivatized prior to gas chromatographic analysis.

Phenols and sugars: Only one laboratory reported values (all less than their detection limits) for the phenols in Air Particulate I while for the PM2.5 Interim RM, one laboratory reported data for isoeugenol (4129 ng/g), and another laboratory reported data for all of the phenols on the list (with isoeugenol at <159 ng/g). The only sugar on the target analyte list currently is levoglucosan. For Air Particulate I, one laboratory reported a value of 10427 ng/g while another laboratory reported < 2000000 ng/g. For the PM2.5 Interim RM, three laboratories reported data for levoglucosan, but the relative standard deviation of the consensus value is large (83 %). These polar compounds present challenges similar to those of the carbonyls and acids.

PM2.5 Interim RM

The particulate matter used in Trial II is intended for use as a control material for laboratories conducting ongoing PM2.5 analyses until a larger collection of PM2.5 is completed and processed as an SRM. To this end, the data from Trial II were used to value assign concentrations for the majority of the PAHs and nitrated-PAHs as shown in Table 16. The data used in the value assignment included the values from the NIST laboratories (designated as laboratory 1 and laboratory 13) as single sets of data along with the assigned values from the interlaboratory study (excluding the NIST values) as an additional data set. As discussed above for the remaining compounds, either very few laboratories returned data, or there was a large spread in the data received. There were two compounds with relative uncertainties of the assigned values of less than 1 %: indeno[1,2,3cd pyrene and 2-nitrofluoranthene. This small uncertainty is probably not realistic and would be expanded if the material were going to become an SRM. At the other end of the spectrum, there were six compounds with relative uncertainties of the assigned values greater than 30 %: naphthalene, 1-methylphenanthrene, 3-methylphenanthrene, dibenz[a,h]anthracene, coronene, and 7nitrobenz[a]anthracene. The interlaboratory data for naphthalene tended to be scattered and lower than the data obtained in the NIST analyses. The 1-methylphenanthrene and 3-methylphenanthrene values are a combination of three NIST values. For both of the compounds, two of the values agreed well with each other while the third was 50 % to 75 % higher than the other two values. For dibenz[a,h]anthracene, the interlaboratory data were sparse due to reported coelutions with dibenz[a,c]anthracene. The laboratories not reporting coelutions tended to be 60 % lower than the values determined at NIST. For the 7-nitrobenz[a]anthracene, there were only three values reported, not agreeing with each other. The assigned values will be useful for those laboratories who want to use the PM2.5 Interim RM as a control material. As more laboratories generate data, the assigned values will be revised, and additional analytes will be value assigned.

Conclusions and Recommendations

Comparing the data received for the Air Particulate Extract and Air Particulate I, the extraction of samples was not a point of major differences among the laboratories so extracts will not be included for future studies. For the PAHs and nitrated-PAHs, the agreement among the laboratories submitting data was generally good except for those compounds with known coelutions. Neat chemicals of known purity and well-characterized solutions are available for the PAHs. For the nitrated-PAHs, only a limited number of laboratories experienced in this area submitted data. The data received for the remaining classes of compounds showed a wide variation. This variation is probably due to a number of factors, including modifications needed in the extraction and isolation methods used for more polar compounds, mass spectral fragmentation, and chromatographic interferences. For a number of these compounds, there is also a lack of commercially available neat compounds or solutions of the compounds of known purity. An effort is currently underway at NIST to produce calibration solution SRMs for a number of the compounds and labeled analogues. As they become available, these calibration solutions will be provided to the participants. Analytical methods are also being discussed at the working group meetings. As more calibration solutions become available and as methods improve, more laboratories will submit data for the additional compound classes.

Acknowledgments

The time and efforts of the analysts and management of the participating laboratories and the assistance of the NIST Standard Reference Materials Program with the procurement and preparation of the exercise materials are gratefully acknowledged.

Disclaimer

Certain commercial equipment, instruments, or materials are identified in this report to specify adequately the experimental procedure. Such identification does not imply recommendation or endorsement by the National Institute of Standards and Technology, nor does it imply that the materials or equipment identified are the best available for the purpose.

Appendix A Description of Materials and Reporting Instructions Accompanying Samples

Intercomparison Exercise: Air Particulate Extract I and Air Particulate I Description of Materials and Instructions

Intercomparison Exercise Materials:

QA01EXT01 (Air Particulate Extract I) QA01APT01 (Air Particulate I)

For the QA01EXT01 (Air Particulate Extract I), each of the five ampoules contains approximately 1.2 mL of Air Particulate Extract I. This extract was prepared by extracting Air Particulate I (also included in the shipment) using dichloromethane. Each 1 mL of extract represents 0.1 g of Air Particulate I. This material has not been enriched or spiked. Each 2 mL ampoule is labeled with an individual ampoule number as well as the above name.

For QA01APT01 (Air Particulate I), each bottle contains approximately 0.5 g of Air Particulate I. This material is a bulk portion of SRM 1649a that has been sieved to <63 μ m. This material has also not been enriched or spiked. Each bottle is labeled with an individual jar number as well as the above name.

In addition, three concurrent analyses of SRM 1649a, Urban Dust, are recommended. One bottle containing approximately 0.5 g of this material is included in the shipment.

Instructions for Use:

Please analyze three samples of Air Particulate Extract I, Air Particulate I, and SRM 1649a, using your laboratory's and/or program's analytical protocols, for the concentrations (mass/mass) of the analytes listed in Table 1. If your laboratory is not analyzing some of these compounds in the PM 2.5 program, then you do not need to report values for this exercise. There is space provided at the bottom of the spreadsheet to report additional analytes of interest to your program. Please provide data for all of the compounds that your laboratory is quantifying in the PM 2.5 program. All data received will be summarized.

The concentration range for some of the most abundant PAHs of interest (phenanthrene, fluoranthene, pyrene, and benzo[a]pyrene) in SRM 1649a is approximately 2.5 mg/kg to 6.5 mg/kg. Note that the PAH concentrations in Air Particulate I are expected to be in a similar range.

Reporting of Results:

Please report one result, as if three figures were significant, for each of the analytes in each of the three replicates of the Air Particulate Extract I, Air Particulate I, and SRM 1649a. Report results in units of ng/g solution for the extract and ng/g as received for the air particulate samples. If your analysis of the extract is based on a mass /volume basis, please convert to mass/mass by using the density of the solution. Report the density that was used for the conversion. Report the date of measurement of each sample in the requested m/d/y format.

We recognize that the reported concentrations for some of the requested determinands will probably include concentrations of compounds reported to coelute with the determinand of interest with methods commonly in use. Please note at the bottom of your table of reported results if any coelution qualifiers are applicable to your data. Please note that any changes you make to the column or row headings within the tables will **not** be seen by the coordinators because only the table entries and comments at the bottom of the tables are automatically transferred to the exercise database.

We prefer that concentration values be reported for each analyte determined. If the measured concentration is below your typical reporting concentration for an analyte in a particular matrix, you can report the number and list the appropriate detection limit, quantification limit, etc. at the bottom of the data table. However, if you need to report non-numerical data please use the following conventions:

NA "Not analyzed", "not determined"

<"value" "Less than specified concentration", e.g., <8 ng/g

Other "Other"; add note of explanation at end of data table, e.g., interference DL "Below detection limit" may be used, however, <"value" is preferable

Do not use negative numbers or parentheses to indicate "less than detection limits".

The enclosed floppy diskette (DOS format) contains an EXCEL file, APT01.xls. If you have any software/hardware conversion problems, please contact Michele Schantz. The data file templates also include places for you to list the surrogate/internal standards and type of calibration curve used, and to provide a brief description of the analyses. Please **do not** add Aspaces≅ before entering numbers in the table cells and enter them as "numbers" not as "labels". Please **do not** insert any columns or rows **within** the table in the data file. If you wish to include additional data and/or other information or comments, you may add it to the bottom of the data table in the diskette file or send it in hard copy. A printout of the data file format is shown in Table 2.

Submit your results either via diskette file or as an attached file via e-mail (preferred) to:

Michele M. Schantz NIST 100 Bureau Drive Stop 8392 Gaithersburg, MD 20899-8392

E-mail:

michele.schantz@nist.gov

The deadline for receipt of data is April 30, 2001.

Further Information:

If you need further information, please contact Michele at the address listed above or at the following

## Intercomparison Exercise: PM 2.5 Interim RM Description of Materials and Instructions

#### **Intercomparison Exercise Materials:**

#### PM 2.5 Interim RM

Each bottle contains approximately 100 mg of the PM 2.5 Interim Reference Material (RM). This material was collected in Baltimore City with an inlet designed to collect particles less than 1.7  $\mu$ m. This material has not been enriched or spiked. Each bottle is labeled with an individual jar number as well as the above name.

In addition, one bottle of SRM 1649a containing approximately 0.5 g is included in the shipment.

#### **Instructions for Use:**

Please analyze three samples each of PM 2.5 Interim RM and SRM 1649a, using your laboratory's and/or program's analytical protocols, for the concentrations (mass/mass) of the analytes listed in Table 1. If your laboratory is not analyzing some of these compounds in the PM 2.5 program, then you do not need to report values for this exercise. There is space provided at the bottom of the spreadsheet to report additional analytes of interest to your program. Please provide data for all of the compounds that your laboratory is quantifying in the PM 2.5 program. All data received will be summarized.

The concentration range for some of the most abundant PAHs of interest (phenanthrene, fluoranthene, pyrene, and benzo[a]pyrene) in SRM 1649a is approximately 2.5 mg/kg to 6.5 mg/kg. Note that based on a preliminary analysis, the PAH concentrations in PM 2.5 Interim RM are expected to be in a similar range.

#### **Reporting of Results:**

Please report one result, as if three figures were significant, for each of the analytes in each of the three replicates of the PM 2.5 Interim RM and SRM 1649a. Report results in units of ng/g as received for the air particulate samples. Be sure to keep the bottles well sealed and bring to room temperature before weighing if stored in the refrigerator or freezer. Report the date of measurement of each sample in the requested m/d/y format.

We recognize that the reported concentrations for some of the requested analytes will probably include concentrations of compounds reported to coelute with the analyte of interest with methods commonly in use. Please note at the bottom of your table of reported results if any

coelution qualifiers are applicable to your data. Please note that any changes that you make to the column or row headings **within** the tables will **not** be seen by the coordinators because only the table entries and comments at the bottom of the tables are automatically transferred to the exercise database. Please do not add or delete lines from the spreadsheet.

We prefer that concentration values be reported for each analyte determined. If the measured concentration is below your typical reporting concentration for an analyte in a particular matrix, you can report the number and list the appropriate detection limit, quantification limit, etc. at the bottom of the data table. However, if you need to report non-numerical data please use the following conventions:

NA "Not analyzed", "not determined"

<"value" "Less than specified concentration", e.g., <8 ng/g

Other "Other"; add note of explanation at end of data table, e.g., interference DL "Below detection limit" may be used, however, <"value" is preferable

Do not use negative numbers or parentheses to indicate "less than detection limits".

An EXCEL file, APT02.xls, has been sent as an e-mail attachment to you. If you have any software/hardware conversion problems, please contact Michele Schantz. The data file templates also include places for you to list the surrogate/internal standards and type of calibration curve used, and to provide a brief description of the analyses. Please **do not** add Aspaces≅ before entering numbers in the table cells and enter them as "numbers" not as "labels". Please **do not** insert any columns or rows **within** the table in the data file. If you wish to include additional data and/or other information or comments, you may add it to the bottom of the data table in the diskette file or send it in hard copy. A printout of the data file format is shown in Table 2.

Submit your results as an attached file via e-mail (preferred) to:

E-mail: michele.schantz@nist.gov

The deadline for receipt of data is July 31, 2002.

#### Further Information:

If you need further information, please contact Michele at the e-mail listed above or at the

following phone numbers: Phone: (301)975-3106

FAX: (301)977-0685
